

ADC121S655

12-Bit, 200 kSPS to 500 kSPS, Differential Input, Micro Power A/D Converter

General Description

The ADC121S655 is a 12-bit, 200 kSPS to 500 kSPS sampling Analog-to-Digital (A/D) converter that features a fully differential, high impedance analog input and an external reference. The reference voltage can be varied from 1.0V to V_A , with a corresponding resolution between 244 μ V and V_A divided by 4096.

The output serial data is binary 2's complement and is compatible with several standards, such as SPI™, QSPI™, MICROWIRE™, and many common DSP serial interfaces. The differential input, low power consumption, and small size make the ADC121S655 ideal for direct connection to transducers in battery operated systems or remote data acquisition applications.

Operating from a single 5V supply, the supply current when operating at 500 kSPS is typically 1.8 mA. The supply current drops down to 0.3 μ A typically when the ADC121S655 enters power-down mode. The ADC121S655 is available in the MSOP-8 package. Operation is guaranteed over the industrial temperature range of -40°C to $+105^{\circ}\text{C}$ and clock rates of 3.2 MHz to 8 MHz.

Features

- True Differential Inputs
- Guaranteed performance from 200 kSPS to 500 kSPS
- External Reference
- Wide Input Common-Mode Voltage Range
- SPI™/QSPI™/MICROWIRE™/DSP compatible Serial Interface

Key Specifications

■ Conversion Rate	200 kSPS to 500 kSPS
■ INL	± 0.95 LSB (max)
■ DNL	± 0.85 LSB (max)
■ Offset Error	± 3.0 LSB (max)
■ Gain Error	± 5.5 LSB (max)
■ SINAD	70 dB (min)
■ Power Consumption at $V_A = 5\text{V}$	
■ — Active, 500 kSPS	9 mW (typ)
■ — Active, 200 kSPS	7 mW (typ)
■ — Power-Down	1.5 μ W (typ)

Applications

- Automotive Navigation
- Portable Systems
- Medical Instruments
- Instrumentation and Control Systems
- Motor Control
- Direct Sensor Interface

Pin-Compatible Alternatives by Speed

All devices are pin compatible.

Resolution	Specified for Sample Rate Range of:		
	50 to 200 kSPS	200 to 500 kSPS	500 kSPS to 1 MSPS
12-bit	ADC121S625	ADC121S655	ADC121S705

Absolute Maximum Ratings (Notes 1, 2)

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.

Analog Supply Voltage V_A	-0.3V to 6.5V
Voltage on Any Pin to GND	-0.3V to ($V_A + 0.3V$)
Input Current at Any Pin (Note 3)	± 10 mA
Package Input Current (Note 3)	± 50 mA
Power Consumption at $T_A = 25^\circ\text{C}$	See (Note 4)
ESD Susceptibility (Note 5)	
Human Body Model	2500V
Machine Model	250V
Charge Device Model	750V
Junction Temperature	$+150^\circ\text{C}$
Storage Temperature	-65°C to $+150^\circ\text{C}$

Operating Ratings (Notes 1, 2)

Operating Temperature Range	$-40^\circ\text{C} \leq T_A \leq +105^\circ\text{C}$
Supply Voltage, V_A	+4.5V to +5.5V
Reference Voltage, V_{REF}	1.0V to V_A
Input Common-Mode Voltage, V_{CM}	See Figure 8 (Sect 2.3)
Digital Input Pins Voltage Range	0 to V_A
Clock Frequency	3.2 MHz to 8 MHz
Differential Analog Input Voltage	$-V_{REF}$ to $+V_{REF}$

Package Thermal Resistance

Package	θ_{JA}
8-lead MSOP	$200^\circ\text{C} / \text{W}$

Soldering process must comply with National Semiconductor's Reflow Temperature Profile specifications. Refer to www.national.com/packaging. (Note 6)

ADC121S655 Converter Electrical Characteristics (Note 8)

The following specifications apply for $V_A = +4.5V$ to $5.5V$, $V_{REF} = 2.5V$, $f_{SCLK} = 3.2$ to 8 MHz, $f_{IN} = 100$ kHz, $C_L = 25$ pF, unless otherwise noted. **Boldface limits apply for $T_A = T_{MIN}$ to T_{MAX}** ; all other limits are at $T_A = 25^\circ\text{C}$.

Symbol	Parameter	Conditions	Typical	Limits	Units (Note 7)
STATIC CONVERTER CHARACTERISTICS					
	Resolution with No Missing Codes			12	Bits

t_{AD}	Aperture Delay	See the Specification Definitions	6		ns

ADC121S655 Timing Specifications (Note 8)

The following specifications apply for $V_A = +4.5V$ to $5.5V$, $V_{REF} = 2.5V$, $f_{SCLK} = 3.2$ MHz to 8 MHz, $C_L = 25$ pF, **Boldface limits apply for $T_A = T_{MIN}$ to T_{MAX}** ; all other limits $T_A = 25^\circ C$.

Symbol	Parameter	Conditions	Typical	Limits	Units
t_{CSH}	\overline{CS} Hold Time after an SCLK rising edge			5	ns (min)
t_{CSSU}	\overline{CS} Setup Time prior to an SCLK rising edge			5	ns (min)
t_{DH}	D_{OUT} Hold time after an SCLK Falling edge		7	2.5	ns (min)
t_{DA}	D_{OUT} Access time after an SCLK Falling edge		18	22	ns (max)
t_{DIS}	D_{OUT} Disable Time after the rising edge of \overline{CS} (Note 10)			20	ns (max)
t_{EN}	D_{OUT} Enable Time after the falling edge of \overline{CS}		8	20	ns (max)
t_{CH}	SCLK High Time			25	ns (min)
t_{CL}	SCLK Low Time			25	ns (min)
t_r	D_{OUT} Rise Time		7		ns
t_f	D_{OUT} Fall Time		7		ns

Note 1: Absolute Maximum Ratings indicate limits beyond which damage to the device may occur. Operating Ratings indicate conditions for which the device is functional, but do not guarantee specific performance limits. For guaranteed specifications and test conditions, see the Electrical Characteristics. The guaranteed specifications apply only for the test conditions listed. Some performance characteristics may degrade when the device is not operated under the listed test conditions. Operation of the device beyond the maximum Operating Ratings is not recommended.

Note 2: All voltages are measured with respect to GND = 0V, unless otherwise specified.

Note 3: When the input voltage at any pin exceeds the power supplies (that is, $V_{IN} < GND$ or $V_{IN} > V_A$), the current at that pin should be limited to 10 mA. The 50 mA maximum package input current rating limits the number of pins that can safely exceed the power supplies with an input current of 10 mA to five.

Note 4: The absolute maximum junction temperature ($T_{J,max}$) for this device is $150^\circ C$. The maximum allowable power dissipation is dictated by $T_{J,max}$, the junction-to-ambient thermal resistance (θ_{JA}), and the ambient temperature (T_A), and can be calculated using the formula $P_{D,MAX} = (T_{J,max} - T_A)/\theta_{JA}$. The values for maximum power dissipation listed above will be reached only when the ADC121S655 is operated in a severe fault condition (e.g. when input or output pins are driven beyond the power supply voltages, or the power supply polarity is reversed). Such conditions should always be avoided.

Note 5: Human body model is a 100 pF capacitor discharged through a 1.5 k Ω resistor. Machine model is a 220 pF capacitor discharged through 0 Ω . Charge device model simulates a pin slowly acquiring charge (such as from a device sliding down the feeder in an automated assembler) then rapidly being discharged.

Note 6: Reflow temperature profiles are different for lead-free packages.

Note 7: Tested limits are guaranteed to National's AOQL (Average Outgoing Quality Level).

Note 8: Data sheet min/max specification limits are guaranteed by design, test, or statistical analysis.

Note 9: While the maximum sample rate is $f_{SCLK}/16$, the actual sample rate may be lower than this by having the \overline{CS} rate slower than $f_{SCLK}/16$.

Note 10: t_{DIS} is the time for D_{OUT} to change 10% while being loaded by the Timing Test Circuit.

FIGURE 7. Voltage Waveform for t_{DIS}

Specification Definitions

APERTURE DELAY is the time between the fourth falling edge of SCLK and the time when the input signal is acquired or held for conversion.

COMMON MODE REJECTION RATIO (CMRR) is a measure of how well in-phase signals common to both input pins are rejected.

To calculate CMRR, the change in output offset is measured while the common mode input voltage is changed from 2V to 3V.

$$\text{CMRR} = 20 \text{ LOG} (\Delta \text{ Common Input} / \Delta \text{ Output Offset})$$

CONVERSION TIME is the time required, after the input voltage is acquired, for the ADC to convert the input voltage to a digital word.

DIFFERENTIAL NON-LINEARITY (DNL) is the measure of the maximum deviation from the ideal step size of 1 LSB.

DUTY CYCLE is the ratio of the time that a repetitive digital waveform is high to the total time of one period. The specification here refers to the SCLK.

EFFECTIVE NUMBER OF BITS (ENOB, or EFFECTIVE BITS) is another method of specifying Signal-to-Noise and Distortion or SINAD. ENOB is defined as $(\text{SINAD} - 1.76) / 6.02$ and says that the converter is equivalent to a perfect ADC of this (ENOB) number of bits.

FULL POWER BANDWIDTH is a measure of the frequency at which the reconstructed output fundamental drops 3 dB below its low frequency value for a full scale input.

GAIN ERROR is the deviation from the ideal slope of the transfer function. It is the difference between Positive Full-Scale Error and Negative Full-Scale Error and can be calculated as:

$$\text{Gain Error} = \text{Positive Full-Scale Error} - \text{Negative Full-Scale Error}$$

INTEGRAL NON-LINEARITY (INL) is a measure of the deviation of each individual code from a line drawn from negative full scale ($1/2$ LSB below the first code transition) through positive full scale ($1/2$ LSB above the last code transition). The deviation of any given code from this straight line is measured from the center of that code value.

MISSING CODES are those output codes that will never appear at the ADC outputs. The ADC121S655 is guaranteed not to have any missing codes.

NEGATIVE FULL-SCALE ERROR is the difference between the differential input voltage at which the output code transi-

tions from negative full scale to the next code and $-V_{\text{REF}} + 0.5$ LSB

OFFSET ERROR is the difference between the differential input voltage at which the output code transitions from code 000h to 001h and $1/2$ LSB.

POSITIVE FULL-SCALE ERROR is the difference between the differential input voltage at which the output code transitions to positive full scale and V_{REF} minus 1.5 LSB.

POWER SUPPLY REJECTION RATIO (PSRR) is a measure of how well a change in supply voltage is rejected. PSRR is calculated from the ratio of the change in offset error for a given change in supply voltage, expressed in dB. For the ADC121S655, V_A is changed from 4.5V to 5.5V.

$$\text{PSRR} = 20 \text{ LOG} (\Delta \text{Offset} / \Delta V_A)$$

SIGNAL TO NOISE RATIO (SNR) is the ratio, expressed in dB, of the rms value of the input signal to the rms value of the sum of all other spectral components below one-half the sampling frequency, not including harmonics or d.c.

SIGNAL TO NOISE PLUS DISTORTION (S/N+D or SINAD) is the ratio, expressed in dB, of the rms value of the input signal to the rms value of all of the other spectral components below half the clock frequency, including harmonics but excluding d.c.

SPURIOUS FREE DYNAMIC RANGE (SFDR) is the difference, expressed in dB, between the desired signal amplitude to the amplitude of the peak spurious spectral component, where a spurious spectral component is any signal present in the output spectrum that is not present at the input and may or may not be a harmonic.

TOTAL HARMONIC DISTORTION (THD) is the ratio of the rms total of the first five harmonic components at the output to the rms level of the input signal frequency as seen at the output, expressed in dB. THD is calculated as

$$\text{THD} = 20 \cdot \log_{10} \sqrt{\frac{A_{f2}^2 + \dots + A_{f6}^2}{A_{f1}^2}}$$

where A_{f1} is the RMS power of the input frequency at the output and A_{f2} through A_{f6} are the RMS power in the first 5 harmonic frequencies.

THROUGHPUT TIME is the minimum time required between the start of two successive conversion.

Typical Performance Characteristics $V_A = 5.0V$, $V_{REF} = 2.5V$, $T_A = +25^\circ C$, $f_{SAMPLE} = 500$ kSPS, $f_{SCLK} = 8$ MHz, $f_{IN} = 100$ kHz unless otherwise stated.

Functional Description

The ADC121S655 analog-to-digital converter uses a successive approximation register (SAR) architecture based upon capacitive redistribution containing an inherent sample/hold function. The architecture and process allow the ADC121S655 to acquire and convert an analog signal at sample rates up to 500 kSPS while consuming very little power.

The ADC121S655 requires an external reference, external clock, and a single +5V power source that can be as low as +4.5V. The external reference can be any voltage between 1V and V_A . The value of the reference voltage determines the range of the analog input, while the reference input current depends upon the conversion rate.

The external clock can take on values as indicated in the Electrical Characteristics Table of this data sheet. The duty cycle of the clock is essentially unimportant, provided the minimum clock high and low times are met. The minimum clock frequency is set by internal capacitor leakage. Each conversion requires 16 SCLK cycles to complete. If less than 12 bits of conversion data are required, \overline{CS} can be brought high at any point during the conversion. This procedure of terminating a conversion prior to completion is often referred to as short cycling.

The analog input is presented to the two input pins: +IN and -IN. Upon initiation of a conversion, the differential input at these pins is sampled on the internal capacitor array. The inputs are disconnected from the internal circuitry while a conversion is in progress.

The digital conversion result is clocked out by the SCLK input and is provided serially, most significant bit first, at the D_{OUT} pin. The digital data that is provided at the D_{OUT} pin is that of the conversion currently in progress. With \overline{CS} held low after the conversion is complete, the ADC121S655 continuously converts the analog input. The digital data on D_{OUT} can be clocked into the receiving device on the SCLK rising edges. See the Digital Interface section and timing diagram for more information.

1.0 REFERENCE INPUT

The externally supplied reference voltage sets the analog input range. The ADC121S655 will operate with a reference voltage in the range of 1V to V_A .

As the reference voltage is reduced, the range of input voltages corresponding to each digital output code is reduced. That is, a smaller analog input range corresponds to one LSB (Least Significant Bit). The size of one LSB is equal to twice the reference voltage divided by 4096. When the LSB size goes below the noise floor of the ADC121S655, the noise will span an increasing number of codes and overall performance will suffer. For example, dynamic signals will have their SNR degrade, while D.C. measurements will have their code uncertainty increase. Since the noise is Gaussian in nature, the

effects of this noise can be reduced by averaging the results of a number of consecutive conversions.

Additionally, since offset and gain errors are specified in LSB, any offset and/or gain errors inherent in the A/D converter will increase in terms of LSB size as the reference voltage is reduced.

The reference input and the analog inputs are connected to the capacitor array through a switch matrix when the input is sampled. Hence, the only current required at the reference and at the analog inputs is a series of transient spikes.

Lower reference voltages will decrease the current pulses at the reference input and will slightly decrease the average input current. The reference current changes only slightly with temperature. See the curves, "Reference Current vs. SCLK Frequency" and "Reference Current vs. Temperature" in the Typical Performance Curves section for additional details.

2.0 ANALOG SIGNAL INPUTS

The ADC121S655 has a differential input, and the effective input voltage that is digitized is (+IN) - (-IN). As is the case with all differential input A/D converters, operation with a fully differential input signal or voltage will provide better performance than with a single-ended input. Yet, the ADC121S655 can be presented with a single-ended input.

The current required to recharge the input sampling capacitor will cause voltage spikes at +IN and -IN. Do not try to filter out these noise spikes. Rather, ensure that the transient settles out during the acquisition period (three SCLK cycles after the fall of \overline{CS}).

2.1 Differential Input Operation

With a fully differential input voltage or signal, a positive full scale output code (0111 1111 1111b or 7FFh) will be obtained when (+IN) - (-IN) $\geq V_{REF} - 1.5$ LSB. A negative full scale code (1000 0000 0000b or 800h) will be obtained when (+IN) - (-IN) $\leq -V_{REF} + 0.5$ LSB. This ignores gain, offset and linearity errors, which will affect the exact differential input voltage that will determine any given output code.

2.2 Single-Ended Input Operation

For single-ended operation, the non-inverting input (+IN) of the ADC121S655 should be driven with a signal or voltages that have a maximum to minimum value range that is equal to or less than twice the reference voltage. The inverting input (-IN) should be biased at a stable voltage that is halfway between these maximum and minimum values.

Since the design of the ADC121S655 is optimized for a differential input, the performance degrades slightly when driven with a single-ended input. Linearity characteristics such as INL and DNL typically degrade by 0.1 LSB and dynamic characteristics such as SINAD typically degrades by 2 dB. Note that single-ended operation should only be used if the performance degradation (compared with differential operation) is acceptable.

2.3 Input Common Mode Voltage

The allowable input common mode voltage (V_{CM}) range depends upon the supply and reference voltages used for the ADC121S655. The ranges of V_{CM} are depicted in *Figure 8* and *Figure 9*. The minimum and maximum common mode voltages for differential and single-ended operation are shown in *Table 1*.

FIGURE 8. V_{CM} range for Differential Input operation

FIGURE 9. V_{CM} range for single-ended operation

TABLE 1. Allowable V_{CM} Range

Input Signal	Minimum V_{CM}	Maximum V_{CM}
Differential	$V_{REF} / 2$	$V_A - V_{REF} / 2$
Single-Ended	V_{REF}	$V_A - V_{REF}$

3.0 SERIAL DIGITAL INTERFACE

The ADC121S655 communicates via a synchronous 3-wire serial interface as shown in the Timing Diagram section. \overline{CS} , chip select, initiates conversions and frames the serial data transfers. SCLK (serial clock) controls both the conversion process and the timing of serial data. DOUT is the serial data output pin, where a conversion result is sent as a serial data stream, MSB first.

A serial frame is initiated on the falling edge of \overline{CS} and ends on the rising edge of \overline{CS} . The ADC121S655's DOUT pin is in

a high impedance state when \overline{CS} is high and is active when \overline{CS} is low; thus \overline{CS} acts as an output enable.

During the first three cycles of SCLK, the ADC121S655 is in acquisition mode (t_{ACQ}), acquiring the input voltage. For the next thirteen SCLK cycles (t_{CONV}), the conversion is accomplished and the data is clocked out. SCLK falling edges one through four clock out leading zeros while falling edges five through sixteen clock out the conversion result, MSB first. If there is more than one conversion in a frame (continuous conversion mode), the ADC121S655 will re-enter acquisition mode on the falling edge of SCLK after the $N \cdot 16$ th rising edge of SCLK and re-enter the conversion mode on the $N \cdot 16 + 4$ th falling edge of SCLK as shown in *Figure 2*. "N" is an integer value.

The ADC121S655 can enter acquisition mode under three different conditions. The first condition involves \overline{CS} going low (asserted) with SCLK high. In this case, the ADC121S655 enters acquisition mode on the first falling edge of SCLK after \overline{CS} is asserted. In the second condition, \overline{CS} goes low with SCLK low. Under this condition, the ADC121S655 automatically enters acquisition mode and the falling edge of \overline{CS} is seen as the first falling edge of SCLK. In the third condition, \overline{CS} and SCLK go low simultaneously and the ADC121S655 enters acquisition mode. While there is no timing restriction with respect to the falling edges of \overline{CS} and SCLK, see *Figure 6* for setup and hold time requirements for the falling edge of \overline{CS} with respect to the rising edge of SCLK.

3.1 \overline{CS} Input

The \overline{CS} (chip select bar) input is CMOS compatible and is active low. The ADC121S655 is in normal mode when \overline{CS} is low and power-down mode when \overline{CS} is high. \overline{CS} frames the conversion window. The falling edge of \overline{CS} marks the beginning of a conversion and the rising of \overline{CS} marks the end of a conversion window. Multiple conversions can occur within a given conversion frame with each conversion requiring sixteen SCLK cycles.

3.2 SCLK Input

The SCLK (serial clock) is used as the conversion clock and to clock out the conversion results. This input is CMOS compatible. Internal settling time requirements limit the maximum clock frequency while internal capacitor leakage limits the minimum clock frequency. The ADC121S655 offers guaranteed performance with the clock rates indicated in the electrical table.

3.3 Data Output

The output data format of the ADC121S655 is two's complement, as shown in *Table 2*. This table indicates the ideal output code for the given input voltage and does not include the effects of offset, gain error, linearity errors, or noise. Each data output bit is sent on the falling edge of SCLK.

While most receiving systems will capture the digital output bits on the rising edge of SCLK, the falling edge of SCLK may be used to capture each bit if the minimum hold time (t_{DH}) for D_{OUT} is acceptable. See *Figure 5* for DOUT hold and access times.

D_{OUT} is enabled on the falling edge of \overline{CS} and disabled on the rising edge of \overline{CS} . If \overline{CS} is raised prior to the 16th falling edge of SCLK, the current conversion is aborted and D_{OUT} will go into its high impedance state. A new conversion will begin when \overline{CS} is taken LOW.

TABLE 2. Ideal Output Code vs. Input Voltage

Analog Input (+IN) – (–IN)	2's Complement Binary Output	2's Comp. Hex Code	2's Comp. Dec Code
$V_{REF} - 1.5 \text{ LSB}$	0111 1111 1111	7FF	2047
+ 0.5 LSB	0000 0000 0001	001	1
– 0.5 LSB	0000 0000 0000	000	0
0V – 1.5 LSB	1111 1111 1111	FFF	–1
$-V_{REF} + 0.5 \text{ LSB}$	1000 0000 0000	800	–2048

Applications Information

OPERATING CONDITIONS

We recommend that the following conditions be observed for operation of the ADC121S655:

$$-40^{\circ}\text{C} \leq T_A \leq +105^{\circ}\text{C}$$

$$+4.5\text{V} \leq V_A \leq +5.5\text{V}$$

$$1\text{V} \leq V_{REF} \leq V_A$$

$$3.2 \text{ MHz} \leq f_{CLK} \leq 8 \text{ MHz}$$

V_{CM} : See Section 2.3

4.0 POWER CONSUMPTION

The architecture, design, and fabrication process allow the ADC121S655 to operate at conversion rates up to 500 kSPS while consuming very little power. The ADC121S655 consumes the least amount of power while operating in power down mode. For applications where power consumption is critical, the ADC121S655 should be operated in power down mode as often as the application will tolerate. To further reduce power consumption, stop the SCLK while \overline{CS} is high.

4.1 Short Cycling

Another way of saving power is to short cycle the conversion process. This is done by pulling \overline{CS} high after the last required bit is received from the ADC121S655 output. This is possible because the ADC121S655 places the latest converted data bit on D_{OUT} as it is generated. If only 8-bits of the conversion result are needed, for example, the conversion can be terminated by pulling \overline{CS} high after the 8th bit has been clocked out. Halting the conversion after the last needed bit is outputted is called short cycling.

Short cycling can be used to lower the power consumption in those applications that do not need a full 12-bit resolution, or where an analog signal is being monitored until some condition occurs. For example, it may not be necessary to use the full 12-bit resolution of the ADC121S655 as long as the signal being monitored is within certain limits. In some circumstances, the conversion could be terminated after the first few bits. This will lower power consumption in the converter since the ADC121S655 spends more time in power down mode and less time in the conversion mode.

4.2 Burst Mode Operation

Normal operation of the ADC121S655 requires the SCLK frequency to be sixteen times the sample rate and the \overline{CS} rate to be the same as the sample rate. However, in order to minimize power consumption in applications requiring sample rates below 200 kSPS, the ADC121S655 should be run with an SCLK frequency of 8 MHz and a \overline{CS} rate as slow as the system requires. When this is accomplished, the ADC121S655 is operating in burst mode. The ADC121S655 enters into power down mode at the end of each conversion, minimizing power consumption. This causes the converter to spend the longest possible time in power down mode. Since

power consumption scales directly with conversion rate, minimizing power consumption requires determining the lowest conversion rate that will satisfy the requirements of the system.

5.0 TIMING CONSIDERATIONS

Proper operation requires that the fall of \overline{CS} not occur simultaneously with a rising edge of SCLK. If the fall of \overline{CS} occurs during the rising edge of SCLK, the data might be clocked out one bit early. Whether or not the data is clocked out early depends upon how close the \overline{CS} transition is to the SCLK transition, the device temperature, and characteristics of the individual device. To ensure that the data is always clocked out at a given time (the 5th falling edge of SCLK), it is essential that the fall of \overline{CS} always meet the timing requirement specified in the Timing Specification table.

6.0 PCB LAYOUT AND CIRCUIT CONSIDERATIONS

For best performance, care should be taken with the physical layout of the printed circuit board. This is especially true with a low reference voltage or when the conversion rate is high. At high clock rates there is less time for settling, so it is important that any noise settles out before the conversion begins.

6.1 Power Supply

Any ADC architecture is sensitive to spikes on the power supply, reference, and ground pins. These spikes may originate from switching power supplies, digital logic, high power devices, and other sources. Power to the ADC121S655 should be clean and well bypassed. A 0.1 μF ceramic bypass capacitor and a 1 μF to 10 μF capacitor should be used to bypass the ADC121S655 supply, with the 0.1 μF capacitor placed as close to the ADC121S655 package as possible.

6.2 Voltage Reference

The reference source must have a low output impedance and needs to be bypassed with a minimum capacitor value of 0.1 μF . A larger capacitor value of 1 μF to 10 μF placed in parallel with the 0.1 μF is preferred. While the ADC121S655 draws very little current from the reference on average, there are higher instantaneous current spikes at the reference input that must settle out while SCLK is high. Since these transient spikes can be as high as 20 mA, it is important that the reference circuit be capable of providing this much current and settle out during the first three clock periods (acquisition time).

The reference input of the ADC121S655, like all A/D converters, does not reject noise or voltage variations. Keep this in mind if the reference voltage is derived from the power supply. Any noise and/or ripple from the supply that is not rejected by the external reference circuitry will appear in the digital results. The use of an active reference source is recommended. The LM4040 and LM4050 shunt reference families and the LM4132 and LM4140 series reference families are excellent choices for a reference source.

6.3 Power and Ground Planes

A single ground plane and the use of two or more power planes is recommended. The power planes should all be in the same board layer and will define the analog, digital, and high power board areas. Lines associated with these areas should always be routed within their respective areas.

The GND pin on the ADC121S655 should be connected to the ground plane at a quiet point. Avoid connecting the GND pin too close to the ground point of a microprocessor, microcontroller, digital signal processor, or other high power digital device.

7.0 APPLICATION CIRCUITS

The following figures are examples of the ADC121S655 in typical application circuits. These circuits are basic and will generally require modification for specific circumstances.

7.1 Data Acquisition

Figure 10 shows a typical connection diagram for the ADC121S655 operating at a supply voltage of +5V. A 5 to 10 ohm resistor is shown between the supply pin of the ADC121S655 and the microcontroller to low pass filter any high frequency noise present on the supply line. The reference pin, V_{REF} , is connected to a 2.5V shunt reference, the LM4040-2.5, to define the analog input range of the ADC121S655 independent of supply variation on the +5V supply line. The V_{REF} pin should be de-coupled to the ground plane by a 0.1 uF ceramic capacitor and a tantalum capacitor of at least 4.7 uF. It is important that the 0.1 uF capacitor be placed as close as possible to the V_{REF} pin while the placement of the tantalum capacitor is less critical. It is also recommended that the supply pin of the ADC121S655 be de-coupled to ground by a 1 uF capacitor.

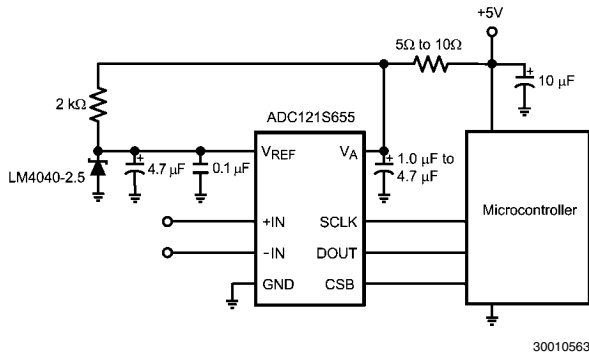

FIGURE 10. Low cost, low power Data Acquisition System

7.2 Pressure Sensor

Figure 11 shows an example of interfacing a pressure sensor to the ADC121S655. A digital-to-analog converter (DAC) is used to bias the pressure sensor. The DAC081S101 provides a means for dynamically adjusting the sensitivity of the sensor. A shunt reference voltage of 2.5V is used as the reference for the ADC121S655. The ADC121S655, DAC081S101, and the LM4040 are all powered from the same voltage source.
