#### Description

The CY29948 is a low-voltage 200-MHz clock distribution buffer with the capability to select either a differential LVPECL or a LVCMOS/LVTTL compatible input clock. The two clock sources can be used to provide for a test clock as well as the primary system clock. All other control inputs are LVCMOS/LVTTL compatible. The 12 outputs are LVCMOS or LVTTL compatible and can drive 50Ω series or parallel terminated transmission lines. For series terminated transmission lines, each output can drive one or two traces giving the device an effective fanout of 1:24. The outputs can also be three-stated via the three-state input TS#. Low output-to-output skews make the CY29948 an ideal clock distribution buffer for nested clock trees in the most demanding of synchronous systems.

The CY29948 also provides a synchronous output enable input for enabling or disabling the output clocks. Since this input is internally synchronized to the input clock, potential output glitching or runt pulse generation is eliminated.

**Output Enable/Disable**

The CY29948 features a control input to enable or disable the outputs. This data is latched on the falling edge of the input clock. When SYNC\_OE is asserted LOW, the outputs are disabled in a LOW state. When SYNC\_OE is set HIGH, the outputs are enabled as shown in *Figure 1*.

This device contains circuitry to protect the inputs against damage due to high static voltages or electric field; however, precautions should be taken to avoid application of any voltage higher than the maximum rated voltages to this circuit. For proper operation,  $V_{in}$  and  $V_{out}$  should be constrained to the range:

$$V_{SS} < (V_{in} \text{ or } V_{out}) < V_{DD}$$

Unused inputs must always be tied to an appropriate logic voltage level (either  $V_{SS}$  or  $V_{DD}$ ).

**DC Parameters:**  $V_{DD} = V_{DDC} = 3.3V \pm 10\%$  or  $2.5V \pm 5\%$ , Over the specified temperature range

**Notes:**

- Multiple Supplies:** The voltage on any input or I/O pin cannot exceed the power pin during power-up. Power supply sequencing is NOT required.
- Inputs have pull-up/pull-down resistors that effect input current.
- The  $V_{CMR}$  is the difference from the most positive side of the differential input signal. Normal operation is obtained when the "High" input is within the  $V_{CMR}$  range and the input lies within the  $V_{PP}$  specification.
- Driving series or parallel terminated 50 $\Omega$  (or 50 $\Omega$  to  $V_{DD}/2$ ) transmission lines.
