

## SERIAL INTERFACE CODEC/FILTER WITH RECEIVE POWER AMPLIFIER

- COMPLETE CODEC AND FILTERING SYSTEM INCLUDING :
  - Transmit high-pass and low-pass filtering.
  - Receive low-pass filter with sin x/x correction.
  - Active RC noise filter.
  - $\mu$ -law or A-law compatible CODER and DECODER.
  - Internal precision voltage reference.
  - Serial I/O interface.
  - Internal auto-zero circuitry.
  - Receive push-pull power amplifiers.
- $\mu$ -LAW ETC5064
- A-LAW ETC5067
- MEETS OR EXCEEDS ALL D3/D4 AND CCITT SPECIFICATIONS.
- $\pm 5$  V OPERATION.
- LOW OPERATING POWER-TYPICALLY 70 mW
- POWER-DOWN STANDBY MODE-TYPICALLY 3 mW
- AUTOMATIC POWER DOWN
- TTL OR CMOS COMPATIBLE DIGITAL INTERFACES
- MAXIMIZES LINE INTERFACE CARD CIRCUIT DENSITY
- 0°C TO 70°C OPERATION: ETC5064/67
- -40°C TO 85°C OPERATION: ETC5064-X/67-X

### DESCRIPTION

The ETC5064 ( $\mu$ -law), ETC5067 (A-law) are monolithic PCM CODEC/FILTERS utilizing the A/D and D/A conversion architecture shown in the Block Diagrams and a serial PCM interface. The devices are fabricated using double-poly CMOS process.

Similar to the ETC505X family, these devices feature an additional Receive Power Amplifier to provide push-pull balanced output drive capability. The receive gain can be adjusted by means of two external resistors for an output level of up to  $\pm 6.6$  V across a balanced 600 $\Omega$  load.

Also included is an Analog Loopback switch and TSx output.

## PIN DESCRIPTION

Name	Pin Type (*)	N	Description
VPO <sup>+</sup>	O	1	The Non-inverting Output of the Receive Power Amplifier
GNDA	GND	2	Analog Ground. All signals are referenced to this pin.
VPO <sup>-</sup>	O	3	The Inverting Output of the Receive Power Amplifier
VPI	I	4	Inverting Input to the Receive Power Amplifier. Also powers down both amplifiers when connected to V <sub>BB</sub> .
VF <sub>RO</sub>	O	5	Analog Output of the Receive Filter.
V <sub>CC</sub>	S	6	Positive Power Supply Pin. V <sub>CC</sub> = +5V ±5%
FS <sub>R</sub>	I	7	Receive Frame Sync Pulse which enable BCLK <sub>R</sub> to shift PCM data into D <sub>R</sub> . FS <sub>R</sub> is an 8KHz pulse train. See figures 1 and 2 for timing details.
D <sub>R</sub>	I	8	Receive Data Input. PCM data is shifted into D <sub>R</sub> following the FS <sub>R</sub> leading edge
BCLK <sub>R</sub> /CLKSEL	I	9	The bit Clock which shifts data into D <sub>R</sub> after the FS <sub>R</sub> leading edge. May vary from 64KHz to 2.048MHz. Alternatively, may be a logic input which selects either 1.536MHz/1.544MHz or 2.048MHz for master clock in synchronous mode and BCLK <sub>X</sub> is used for both transmit and receive directions (see table 1). This input has an internal pull-up.
MCLK <sub>R</sub> /PDN	I	10	Receive Master Clock. Must be 1.536MHz, 1.544MHz or 2.048MHz. May be asynchronous with MCLK <sub>X</sub> , but should be synchronous with MCLK <sub>X</sub> for best performance. When MCLK <sub>R</sub> is connected continuously low, MCLK <sub>X</sub> is selected for all internal timing. When MCLK <sub>R</sub> is connected continuously high, the device is powered down.
MCLK <sub>X</sub>	I	11	Transmit Master Clock. Must be 1.536MHz, 1.544MHz or 2.048MHz. May be asynchronous with MCLK <sub>R</sub> .
BCLK <sub>X</sub>	I	12	The bit clock which shifts out the PCM data on D <sub>X</sub> . May vary from 64KHz to 2.048MHz, but must be synchronous with MCLK <sub>X</sub> .
D <sub>X</sub>	O	13	The TRI-STATE <sup>®</sup> PCM data output which is enabled by FS <sub>X</sub> .
FS <sub>X</sub>	I	14	Transmit frame sync pulse input which enables BCLK <sub>X</sub> to shift out the PCM data on D <sub>X</sub> . FS <sub>X</sub> is an 8KHz pulse train. See figures 1 and 2 for timing details.
$\overline{\text{TS}}_X$	O	15	Open drain output which pulses low during the encoder time slot. Must to be grounded if not used.
ANLB	I	16	Analog Loopback Control Input. Must be set to logic '0' for normal operation. When pulled to logic '1', the transmit filter input is disconnected from the output of the transmit preamplifier and connected to the VPO <sup>+</sup> output of the receive power amplifier.
GS <sub>X</sub>	O	17	Analog output of the transmit input amplifier. Used to set gain externally.
VF <sub>XI</sub> <sup>-</sup>	I	18	Inverting input of the transmit input amplifier.
VF <sub>XI</sub> <sup>+</sup>	I	19	Non-inverting input of the transmit input amplifier.
V <sub>BB</sub>	S	20	Negative Power Supply Pin. V <sub>BB</sub> = -5V ±5%

(\*) I: Input, O: Output, S: Power Supply.

TRI-STATE<sup>®</sup> is a trademark of National Semiconductor Corp.

**FUNCTIONAL DESCRIPTION**

**POWER-UP**

When power is first applied, power-on reset circuitry initializes the device and places it into the power-down mode. All non-essential circuits are deactivated and the  $D_X$  and  $V_{FRO}$  outputs are put in high impedance states. To power-up the device, a logical low level or clock must be applied to the  $MCLK_R/PDN$  pin and  $FS_X$  and/or  $FS_R$  pulses must be present. Thus 2 power-down control modes are available. The first is to pull the  $MCLK_R/PDN$  pin high; the alternative is to hold both  $FS_X$  and  $FS_R$  inputs continuously low. The device will power-down approximately 2 ms after the last  $FS_X$  pulse. The TRI-STATE PCM data output,  $D_X$ , will remain in the high impedance state until the second  $FS_X$  pulse.

**SYNCHRONOUS OPERATION**

For synchronous operation, the same master clock and bit clock should be used for both the transmit and receive directions. In this mode, a clock must be applied to  $MCLK_X$  and the  $MCLK_R/PDN$  pin can be used as a power-down control. A low level on  $MCLK_R/PDN$  powers up the device and a high level powers down the device. In either case,  $MCLK_X$  will be selected as the master clock for both the transmit and receive circuits. A bit clock must also be applied to  $BCLK_X$  and the  $BCLK_R/CLKSEL$  can be used to select the proper internal divider for a master clock of 1.536 MHz, 1.544 MHz or 2.048 MHz. For 1.544 MHz operation, the device automatically compensates for the 193rd clock pulse each frame.

With a fixed level on the  $BCLK_R/CLKSEL$  pin,  $BCLK_X$  will be selected as the bit clock for both the transmit and receive directions. Table 1 indicates the frequencies of operation which can be selected, depending on the state of  $BCLK_R/CLKSEL$ . In this synchronous mode, the bit clock,  $BCLK_X$ , may be from 64 kHz to 2.048 MHz, but must be synchronous with  $MCLK_X$ .

**Table 1:** Selection of Master Clock Frequencies.

<b>BCLKR/CLKSEL</b>	<b>Master Clock Frequency Selected</b>	
	<b>ETC5067 ETC5067-X</b>	<b>ETC5064 ETC5064-X</b>
Clocked	2.048MHz	1.536MHz or 1.544MHz
0	1.536MHz or 1.544MHz	2.048MHz
1 (or open circuit)	2.048MHz	1.536MHz or 1.544MHz

Each  $FS_X$  pulse begins the encoding cycle and the PCM data from the previous encode cycle is shift out of the enabled  $D_X$  output on the positive edge of  $BCLK_X$ . After 8 bit clock periods, the TRISTATE  $D_X$  output is returned to a high impedance state. With an  $FS_R$  pulse, PCM data is latched via the  $D_R$  input on the negative edge of  $BCLK_X$  (or on  $BCLK_R$  if running).  $FS_X$  and  $FS_R$  must be synchronous with  $MCLK_X/R$ .

**ASYNCHRONOUS OPERATION**

For asynchronous operation, separate transmit and receive clocks may be applied.  $MCLK_X$  and  $MCLK_R$  must be 2.048 MHz for the ETC5067 or 1.536 MHz, 1.544 MHz for the ETC5064, and need not be synchronous. For best transmission performance, however,  $MCLK_R$  should be synchronous with  $MCLK_X$ , which is easily achieved by applying only static logic levels to the  $MCLK_R/PDN$  pin. This will automatically connect  $MCLK_X$  to all internal  $MCLK_R$  functions (see pin description). For 1.544 MHz operation, the device automatically compensates for the 193rd clock pulse each frame.  $FS_X$  starts each encoding cycle and must be synchronous with  $MCLK_X$  and  $BCLK_X$ .  $FS_R$  starts each decoding cycle and must be synchronous with  $BCLK_R$ .  $BCLK_R$  must be a clock, the logic levels shown in Table 1 are not valid in asynchronous mode.  $BCLK_X$  and  $BCLK_R$  may operate from 64kHz to 2.048 MHz.

**SHORT FRAME SYNC OPERATION**

The device can utilize either a short frame sync pulse or a long frame sync pulse. Upon power initialization, the device assumes a short frame mode. In this mode, both frame sync pulses,  $FS_X$  and  $FS_R$ , must be one bit clock period long, with timing relationships specified in figure 2. With  $FS_X$  high during a falling edge of  $BCLK_R$ , the next rising edge of  $BCLK_X$  enables the  $D_X$  TRI-STATE output buffer, which will output the sign bit. The following seven rising edges clock out the remaining seven bits, and the next falling edge disables the  $D_X$  output. With  $FS_R$  high during a falling edge of  $BCLK_R$  ( $BCLK_X$  in synchronous mode), the next falling edge of  $BCLK_R$  latches in the sign bit. The following seven falling edges latch in the seven remaining bits. Both devices may utilize the short frame sync pulse in synchronous or asynchronous operating mode.

**LONG FRAME SYNC OPERATION**

To use the long frame mode, both the frame sync pulses,  $FS_X$  and  $FS_R$ , must be three or more bit clock periods long, with timing relationships specified in figure 3. Based on the transmit frame sync  $FS_X$ , the device will sense whether short or long frame sync

pulses are being used. For 64 kHz operation, the frame sync pulses must be kept low for a minimum of 160 ns (see Fig 1). The  $D_X$  TRI-STATE output buffer is enabled with the rising edge of  $FS_X$  or the rising edge of  $BCLK_X$ , whichever comes later, and the first bit clocked out is the sign bit. The following seven  $BCLK_X$  rising edges clock out the remaining seven bits. The  $D_X$  output is disabled by the falling  $BCLK_X$  edge following the eighth rising edge, or by  $FS_X$  going low, whichever comes later. A rising edge on the receive frame sync pulse,  $FS_R$ , will cause the PCM data at  $D_R$  to be latched in on the next eight falling edges of  $BCLK_R$  ( $BCLK_X$  in synchronous mode). Both devices may utilize the long frame sync pulse in synchronous or asynchronous mode.

#### TRANSMIT SECTION

The transmit section input is an operational amplifier with provision for gain adjustment using two external resistors, see figure 4. The low noise and wide bandwidth allow gains in excess of 20 dB across the audio passband to be realized. The op amp drives a unity gain filter consisting of RC active pre-filter, followed by an eighth order switched-capacitor bandpass filter directly drives the encoder sample-and-hold circuit. The A/D is of companding type according to A-law (ETC5067 and ETC5067-X) or  $\mu$ -law (ETC5064 and ETC5064-X) coding conventions. A precision voltage reference is trimmed in manufacturing to provide an input over load ( $t_{MAX}$ ) of nominally 2.5V peak (see table of Transmission Characteristics). The  $FS_X$  frame sync pulse controls the sampling of the filter output, and then the successive-approximation encoding cycle begins. The 8-bit code is then loaded into a buffer and shifted out through  $D_X$  at the next  $FS_X$  pulse. the total encoding delay will be approximately 165 $\mu$ s (due to the transmit filter) plus 125 $\mu$ s (due to encoding delay), which totals 290 $\mu$ s. Any offset voltage due to the filters or comparator is cancelled by sign bit integration.

#### RECEIVE SECTION

The receive section consist of an expanding DAC which drives a fifth order switched-capacitor low pass filter clocked at 256kHz. The decoder is A-law (ETC5067 and ETC5067-X) or  $\mu$ -law (ETC5064 and ETC5064-X) and the 5 th order low pass filter corrects for the  $\sin x/x$  attenuation due to the 8kHz sample and hold. The filter is then followed by a 2 nd order RC active post-filter and power amplifier capable of driving a 600 $\Omega$  load to a level of 7.2dBm. The receive section is unity-gain. Upon the occurrence of  $FS_R$ , the data at the  $D_R$  input is clocked in on the falling edge of the next eight  $BCLK_R$  ( $BCLK_X$ ) periods. At the end of the decoder time slot, the decoding cycle begins, and 10 $\mu$ s later the decoder DAC output is updated. The total decoder delay is about 10 $\mu$ s (decoder up-date) plus 110 $\mu$ s (filter delay) plus 62.5 $\mu$ s (1/2 frame), which gives approximately 180 $\mu$ s.

#### RECEIVE POWER AMPLIFIERS

Two inverting mode power amplifiers are provided for directly driving a matched line interface transformer. The gain of the first power amplifier can be adjusted to boost the  $\pm 2.5V$  peak output signal from the receive filter up  $\pm 3.3V$  peak into an unbalanced 300 $\Omega$  load, or  $\pm 4.0V$  into an unbalanced 15k $\Omega$  load. The second power amplifier is internally connected in unity-gain inverting mode to give 6dB of signal gain for balanced loads. Maximum power transfer to a 600 $\Omega$  subscriber line termination is obtained by differentially driving a balanced transformer with a  $\sqrt{2} : 1$  turns ratio, as shown in figure 4. A total peak power of 15.6dBm can be delivered to the load plus termination. Both power amplifier can be powered down independently from the PDN input by connecting the VPI input to  $V_{BB}$  saving approximately 12 mW of power.

#### ABSOLUTE MAXIMUM RATINGS

**TRANSMISSION CHARACTERISTICS** (continued).

**DISTORTION**

Symbol	Parameter	Min.	Typ.	Max.	Unit
STD <sub>X</sub> or STD <sub>R</sub>	Signal to Total Distortion (sinusoidal test method)				
	Transmit or Receive Half-channel				dBp (ALAW)
	Level = 3.0 dBm0	33			
	= 0 dBm0 to – 30 dBm0	36			
	= – 40 dBm0	XMT 29			dBc (μLAW)
	= – 55 dBm0	RCV 30			
		XMT 14			
		RCV 15			
SFD <sub>X</sub>	Single Frequency Distortion, Transmit (T <sub>A</sub> = 25°C)			– 46	dB
SFD <sub>R</sub>	Single Frequency Distortion, Receive (T <sub>A</sub> = 25°C)			– 46	dB
IMD	Intermodulation Distortion Loop Around Measurement, VF <sub>XI</sub> <sup>+</sup> = – 4 dBm0 to – 21 dBm0, two Frequencies in the Range 300 Hz-3400 Hz			– 41	dB

**CROSSTALK**

Symbol	Parameter	Min.	Typ.	Max.	Unit
CT <sub>X-R</sub>	Transmit to Receive Crosstalk, 0dBm0 Transmit f = 300 Hz-3400 Hz, D <sub>R</sub> = Steady PCM Code		– 90	– 75	dB
				– 65	dB
CT <sub>R-X</sub>	Receive to Transmit Crosstalk, 0dBm0 Receive Level (note 2) f = 300 Hz-3400 Hz, VF <sub>XI</sub> = 0 V		– 90	– 70	dB
				– 65	dB

**POWER AMPLIFIERS**

Symbol	Parameter	Min.	Typ.	Max.	Unit
V <sub>OL</sub>	Maximum 0 dBm0 Level for Better than ± 0.1 dB Linearity Over the Range 10 dBm0 to + 3 dBm0 (balanced load, R <sub>L</sub> connected between VPO <sup>+</sup> and VPO <sup>–</sup> ) R <sub>L</sub> = 600 Ω R <sub>L</sub> = 1200 Ω R <sub>L</sub> = 30 kΩ	33 3.5 4.0			Vrms
S/D <sub>P</sub>	Signal/Distortion R <sub>L</sub> = 600 Ω, 0 dBm0	50			dB

- Notes :** 1. Measured by extrapolation from the distortion test results.  
2. PPSRX, NPSRX, CTR–X measured with a –50dBm0 activating signal applied at VF<sub>XI</sub><sup>+</sup>

**ENCODING FORMAT AT D<sub>X</sub> OUTPUT**

	A-Law (Including even bit inversion)	μLaw
V <sub>IN</sub> (at GS <sub>X</sub> ) = + Full-scale	1 0 1 0 1 0 1 0	1 0 0 0 0 0 0 0
V <sub>IN</sub> (at GS <sub>X</sub> ) = 0 V	1 1 0 1 0 1 0 1 0 1 0 1 0 1 0 1	1 1 1 1 1 1 1 1 0 1 1 1 1 1 1 1
V <sub>IN</sub> (at GS <sub>X</sub> ) = – Full-scale	0 0 1 0 1 0 1 0	0 0 0 0 0 0 0 0

**APPLICATION INFORMATION**

**POWER SUPPLIES**

While the pins at the ETC506X family are well protected against electrical misure, it is recommended that the standard CMOS practice be followed, ensuring that ground is connected to the device before any other connections are made. In applications where the printed circuit board may be plugged into a "hot" socket with power and clocks already present, an extra long ground pin in the connector should be used.

All ground connections to each device should meet at a common point as close as possible to the GNDA pin. This minimizes the interaction of ground return currents flowing through a common bus impedance. 0.1µF supply decoupling capacitors should be connected from this common ground point to VCC and VBB as close to the device as possible.

For best performance, the ground point of each CODEC/FILTER on a card should be connected to a common card ground in star formation, rather than via a ground bus. This common ground point should be decoupled to VCC and VBB with 10µF capacitors.

For best performance,  $\overline{TS}_x$  should be grounded if not used.

**Figure 4 : Typical Asynchronous Application.**
