Presetable synchronous 4-bit binary counter; synchronous reset

74LV163

FEATURES

- Optimized for low voltage applications: 1.0 to 3.6 V
- Accepts TTL input levels between $V_{CC} = 2.7$ V and $V_{CC} = 3.6$ V
- Typical V_{OLP} (output ground bounce) < 0.8 V at $V_{CC} = 3.3$ V, $T_{amb} = 25^{\circ}\text{C}$
- Typical V_{OHV} (output V_{OH} undershoot) > 2 V at $V_{CC} = 3.3$ V, $T_{amb} = 25^{\circ}\text{C}$
- Synchronous counting and loading
- Two count enable inputs for n-bit cascading
- Positive-edge triggered clock
- Synchronous reset
- Output capability: standard
- I_{CC} category: MSI

DESCRIPTION

The 74LV163 is a low-voltage Si-gate CMOS device and is pin and function compatible with 74HC/HCT163.

The 74LV163 is a synchronous presetable binary counter which features an internal look-head carry and can be used for high-speed counting. Synchronous operation is provided by having all flip-flops

clocked simultaneously on the positive-going edge of the clock (CP). The outputs (Q_0 to Q_3) of the counters may be preset to a HIGH or LOW level. A LOW level at the parallel enable input (\overline{PE}) disables the counting action and causes the data at the data inputs (D_0 to D_3) to be loaded into the counter on the positive-going edge of the clock (providing that the set-up and hold time requirements for \overline{PE} are met). Preset takes place regardless of the levels at count enable inputs (CEP and CET). A low level at the master reset input (\overline{MR}) sets all four outputs of the flip-flops (Q_0 to Q_3) to LOW level after the next positive-going transition on the clock (CP) input (provided that the set-up and hold time requirements for \overline{MR} are met).

This action occurs regardless of the levels at \overline{PE} , CET and CEP inputs. This synchronous reset feature enables the designer to modify the maximum count with only one external NAND gate. The look ahead carry simplifies serial cascading of the counters. Both count enable inputs (CEP and CET) must be HIGH to count. The CET input is fed forward to enable the terminal count output (TC). The TC output thus enabled will produce a HIGH output pulse of a duration approximately equal to a HIGH level output of Q_0 . This pulse can be used to enable the next cascading stage. The maximum clock frequency for the cascaded counters is determined by the CP to TC propagation delay and CEP to CP set-up time, according to the following formula:

$$f_{\max} = \frac{1}{t_{p(\max)}(\text{CP to TC}) + t_{su}(\text{CEP to CP})}$$

QUICK REFERENCE DATA

GND = 0 V; $T_{amb} = 25^{\circ}\text{C}$; $t_r = t_f \leq 2.5$ ns

| SYMBOL | PARAMETER | CONDITIONS | TYPICAL | UNIT |
|-------------------|---|------------------------------------|---------------|------|
| t_{PHL}/t_{PLH} | Propagation delay CP to Q_n CP to TC CET to TC | $C_L = 15$ pF; $V_{CC} = 3.3$ V | 15 18 9 | ns |
| f_{\max} | Maximum clock frequency | | 77 | MHz |
| C_I | Input capacitance | | 3.5 | pF |
| C_{PD} | Power dissipation capacitance per gate | $V_I = \text{GND to } V_{CC}^1$ | 25 | pF |

NOTES:

1. C_{PD} is used to determine the dynamic power dissipation (P_D in μW)

$P_D = C_{PD} \times V_{CC}^2 \times f_i + \sum (C_L \times V_{CC}^2 \times f_o)$ where:

f_i = input frequency in MHz; C_L = output load capacitance in pF;

f_o = output frequency in MHz; V_{CC} = supply voltage in V;

$\sum (C_L \times V_{CC}^2 \times f_o)$ = sum of the outputs.

NOTES:

- Stresses beyond those listed may cause permanent damage to the device. These are stress ratings only and functional operation of the device at these or any other conditions beyond those indicated under “recommended operating conditions” is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.
- The input and output voltage ratings may be exceeded if the input and output current ratings are observed.
