## High Speed, High Gain Bipolar NPN Transistor with Antisaturation Network and Transient Voltage Suppression Capability

The BUD42D is a state-of-the-art bipolar transistor. Tight dynamic characteristics and lot to lot minimum spread make it ideally suitable for light ballast applications.

### Main Features:

- Free Wheeling Diode Built In
- Flat DC Current Gain
- Fast Switching Times and Tight Distribution
- “6 Sigma” Process Providing Tight and Reproducible Parameter Spreads
- Epoxy Meets UL94, VO @ 1/8”
- ESD Ratings: Machine Model, C; >400 V  
Human Body Model, 3B; >8000 V

### Two Versions:

- BUD42D-1: Case 369D for Insertion Mode
- BUD42D, BUD42DT4: Case 369C for Surface Mount Mode

## MAXIMUM RATINGS

Figure 28. Forward Bias Safe Operating Area

Figure 29. Reverse Bias Safe Operating Area

Figure 30. Power Derating

There are two limitations on the power handling ability of a transistor: average junction temperature and second breakdown. Safe operating area curves indicate  $I_C$ - $V_{CE}$  limits of the transistor that must be observed for reliable operation; i.e., the transistor must not be subjected to greater dissipation than the curves indicate. The data of Figure 28 is based on  $T_C = 25^\circ\text{C}$ ;  $T_{j(pk)}$  is variable depending on power level. Second breakdown pulse limits are valid for duty cycles to 10% but must be derated when  $T_C > 25^\circ\text{C}$ . Second Breakdown limitations do not derate like thermal limitations. Allowable current at the voltages shown on

Figure 28 may be found at any case temperature by using the appropriate curve on Figure 30.

$T_{j(pk)}$  may be calculated from the data in Figure 31. At any case temperatures, thermal limitations will reduce the power that can be handled to values less than the limitations imposed by second breakdown. For inductive loads, high voltage and current must be sustained simultaneously during turn-off with the base to emitter junction reverse biased. The safe level is specified as reverse biased safe operating area (Figure 29). This rating is verified under clamped conditions so that the device is never subjected to an avalanche mode.

## Minimum Pad Sizes Recommended for Surface Mounted Applications

## TYPICAL SOLDER HEATING PROFILE

For any given circuit board, there will be a group of control settings that will give the desired heat pattern. The operator must set temperatures for several heating zones, and a figure for belt speed. Taken together, these control settings make up a heating “profile” for that particular circuit board. On machines controlled by a computer, the computer remembers these profiles from one operating session to the next. Figure 32 shows a typical heating profile for use when soldering a surface mount device to a printed circuit board. This profile will vary among soldering systems but it is a good starting point. Factors that can affect the profile include the type of soldering system in use, density and types of components on the board, type of solder used, and the type of board or substrate material being used. This profile shows temperature versus time.

The line on the graph shows the actual temperature that might be experienced on the surface of a test board at or near a central solder joint. The two profiles are based on a high density and a low density board. The Vitronics SMD310 convection/infrared reflow soldering system was used to generate this profile. The type of solder used was 62/36/2 Tin Lead Silver with a melting point between 177–189°C. When this type of furnace is used for solder reflow work, the circuit boards and solder joints tend to heat first. The components on the board are then heated by conduction. The circuit board, because it has a large surface area, absorbs the thermal energy more efficiently, then distributes this energy to the components. Because of this effect, the main body of a component may be up to 30 degrees cooler than the adjacent solder joints.
