## CGS2534/35/36/37

### Memory Array Driving

In order to minimize the total load on the address bus, quite often memory arrays are being driven by buffers while having the inputs of the buffers tied together. Although this practice was feasible in the conventional memory designs, in today's high speed, large buswidth designs which require address fetching at higher speeds, this technique produces many undesired results such as cross-talk and over/undershoot.

CGS2534/35/36/37 Quad 1 to 4 Clock Drivers were designed specifically to address these application issues on high speed, large memory arrays systems.

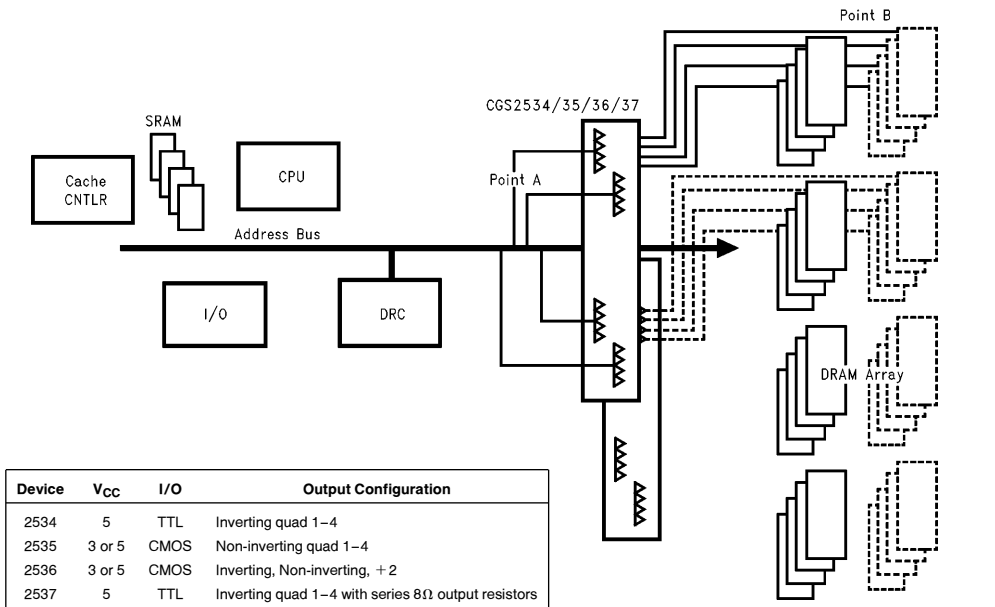

These drivers are optimized to driver large loads, with 3.5 ns propagation delays. These drivers produce less noise while reducing the total capacitive loading on the address bus by having only four inputs tied together (see the diagram below, point A). This helps to minimize the overshoot and undershoot by having only four outputs being switched simultaneously.

Also this larger fan-out helps to save board space since for every one of these drivers, two conventional buffers were typically being used.

Another feature associated with these clock drivers is a 250 ps–500 ps pin-to-pin skew specification. The minimum skew specification allows high speed memory system designers to optimize the performance of their memory subsystem by operating at higher frequencies without having concerns about output-to-output (bank-to-bank) synchronization problem which are associated with driving high capacitive loads (Point B).

The diagram below depicts a "2534/35/36/37" a memory subsystem operating at high speed with large memory capacity. The address bus is common to both the memory and the CPU and I/Os.

These drivers can operate beyond 150 MHz, and are also available in 3V–5V TTL/CMOS versions with large current drive .
